

Radio Engineering Final Exam

Florian Kaltenberger

21.6.2013

1. (a) Consider a mobile receiver that consists has a two-stage low-noise amplifier: The first stage has a noise figure of 3 dB and a gain of 20 dB, and the second amplifier has a gain of 30 dB and a noise figure of 5 dB. What is the noise total figure of the RX?
- (b) The mobile receiver is used for a LTE system with 20MHz bandwidth. Assume that for successful reception an SNR of 0dB is required. What is the thermal noise and what is the receiver sensitivity?
- (c) The mobile receiver should operate in a Rayleigh fading environment with 5% outage probability. Compute the fading margin if the receiver employs a) one antenna and b) two antennas using RSSI based selection combining of the signals.
- (d) Using the computed parameters from above for the two antenna receiver and the following parameters, compute the maximum range of the cell in a noise-limited scenario using the two-path propagation model (d^{-4} law)
 - base station transmit power: 10W
 - base station antenna gain: 12dBi
 - base station feeder loss: 3dB
 - base station height: 15m
 - mobile height: 1.5m
 - mobile antenna gain: -2dB
- (e) Using the same fading margin as above and assuming that the required SIR requirement is the same as the SNR requirement, compute the reuse distance and cluster size in an interference limited scenario.

- (f) For a certain quality of service (QoS), a user requires at least a channel of 2MHz (1/10 of the total available bandwidth)¹. Assuming an Erlang-B system with a blocking probability of 10% and using the computed parameters from above, what is the offered traffic in Erlang per cell? What is the offered traffic in Erlang per km²?
 - (g) The operator decides to upgrade his base stations to sectorized base stations with 3 sectors. What is the offered traffic in Erlang per km² now? What other means are there to increase the throughput?
2. (a) What is multipath propagation and what are its effects? How do we deal with these effects in a wireless system?
 - (b) What is a Power Delay Profile and a Doppler Power Spectrum of a channel? What parameters can be derived from it?
 - (c) What is the coherence bandwidth and the coherence time of a channel? How do they be determined from channel measurements?
 - (d) Give an example of a channel that is not WSS-US and explain why.
 - (e) What is the difference of correlation and mutual coupling in a MIMO channel. What are their effects on the channel capacity.
 - (f) You want to evaluate the performance of a MIMO system that operates mainly indoors with different antenna arrays. What kind of channel model would you use and why?
3. Consider a correlative MIMO channel sounder using a switched antenna. The channel sounder has a bandwidth of 240MHz and operates at a carrier frequency of 5.9 GHz. It uses a correlation sequence of length of $\tau_{\max} = 3.2\mu s$. The time it takes to switch between elements is also $3.2\mu s$. Assume that we use four antenna elements at the transmitter and four at the receiver, what is the total time it takes to measure one MIMO channel? What is the maximum speed we can use in order for the channel to remain identifiable?

¹LTE uses OFDMA, so statically assigning a subset of the available spectrum to a user is not a problem

Erlang B Traffic Table

Maximum Offered Load Versus B and N
